# Meaning function $\mathcal{L}$

- The meaning function  $L$  maps syntax to semantics

$\mathcal{L}(e) = \mathcal{M}$  where  $e$  is a RE and  $\mathcal{M}$  is a set of strings

Therefore:

- $\mathcal{L}(\epsilon) = \{“ ”\}$
- $\mathcal{L}('c') = \{“c”\}$
- $\mathcal{L}(A + B) = \mathcal{L}(A) \cup \mathcal{L}(B)$
- $\mathcal{L}(AB) = \{ab \mid a \in \mathcal{L}(A) \wedge b \in \mathcal{L}(B)\}$
- $\mathcal{L}(A^*) = \{\cup_{i \geq 0} \mathcal{L}(A^i)\}$

# Meaning function $\mathcal{L}$

- Why use a meaning function?
  - Makes clear what is syntax, what is semantics
  - Allows us to consider notation as a separate issue
  - Because expressions and meanings are not 1 to 1
    - consider the case of arabic number and roman numbers

Many different RE can be used to identify the same regular language

It should never happen that the same syntactical structure permits to define more than one meaning

# Meaning function $\mathcal{L}$

- Why use a meaning function?
  - Makes clear what is syntax, what is semantics
  - Allows us to consider notation as a separate issue
  - Because expressions and meanings are not 1 to 1
    - consider the case of arabic number and roman numbers

Many different RE can be used to identify the same regular language

It should never happen that the same syntactical structure permits to define more than one meaning

# Meaning function $\mathcal{L}$

- Why use a meaning function?
  - Makes clear what is syntax, what is semantics
  - Allows us to consider notation as a separate issue
  - Because expressions and meanings are not 1 to 1
    - consider the case of arabic number and roman numbers

Many different RE can be used to identify the same regular language

It should never happen that the same syntactical structure permits to define more than one meaning

# Regular definitions

For notational convention we give names to certain regular expressions. A regular definition, on the alphabet  $\Sigma$  is sequence of definition of the form:

- $d_1 \rightarrow r_1$
- $d_2 \rightarrow r_2$
- ...
- $d_n \rightarrow r_n$

So token of a language can be defined as:

- *letter*  $\rightarrow a|b|\dots|z|A|B|\dots|Z$ 
  - compact syntax:  $[a - zA - B]$
- *digit*  $\rightarrow 0|1|\dots|9$ 
  - compact syntax:  $[0 - 9]$
- *Identifier*  $\rightarrow \textit{letter}(\textit{letter}|\textit{digit})^*$
- *Integer*  $\rightarrow \dots$

# Lexical Specification

- At least one:  $A^+ \equiv AA^*$
- Union:  $A|B \equiv A + B$
- Option:  $A? \equiv A + \epsilon$
- Range:  $'a' + 'b' + \dots + 'z' \equiv [a - z]$
- Excluded range: **complement of**  $[a - z] \equiv [^a - z]$

# Lexical Specification

We want to derive a regular expression for all tokens of a language:

$s \in \mathcal{L}(R)$  – where  $R$  is the RE for all different kind of tokens

How can we define it?

• write a regexp for the lexemes of each token class (number, keyword, identifier,...)

• concatenate the REs for all token classes

• use the union operator to combine the REs for all token classes

• use the union operator to combine the REs for all token classes

• use the union operator to combine the REs for all token classes

• use the union operator to combine the REs for all token classes

# Lexical Specification

We want to derive a regular expression for all tokens of a language:

$s \in \mathcal{L}(R)$  – where  $R$  is the RE for all different kind of tokens

How can we define it?

- 1 write a rexp for the lexemes of each token class (number, keyword, identifier, . . .)
- 2 Constructs  $R$  matching all lexemes for all tokens
- 3 Let input be  $X_1 \dots X_n$   
For  $1 \leq i \leq n$  check if  $X_1 \dots X_i \in \mathcal{L}(R_j)$  for some  $j$
- 4 if success then we know that  $X_1 \dots X_i \in \mathcal{L}(R_j)$  for some  $j$
- 5 remove  $X_1 \dots X_i$  from input and go to (3)

# Lexical Specification

We want to derive a regular expression for all tokens of a language:

$s \in \mathcal{L}(R)$  – where  $R$  is the RE for all different kind of tokens

How can we define it?

- 1 write a rexp for the lexemes of each token class (number, keyword, identifier, . . . )
- 2 Constructs  $R$  matching all lexemes for all tokens
- 3 Let input be  $X_1 \dots X_n$   
For  $1 \leq i \leq n$  check if  $X_1 \dots X_i \in \mathcal{L}(R_j)$  for some  $j$
- 4 if success then we know that  $X_1 \dots X_i \in \mathcal{L}(R_j)$  for some  $j$
- 5 remove  $X_1 \dots X_i$  from input and go to (3)

# Lexical Specification

- 5 remove  $X_1 \dots X_i$  from input and go to (3)

# LA matching rules

Suppose that at the same time for  $i \neq j$ :

- $X_1 \dots X_i \in \mathcal{L}(R)$
- $X_1 \dots X_j \in \mathcal{L}(R)$

Which is the match to consider?

longest match rule

Suppose that at the same time for  $i \neq j \in [1..n]$  and  $R = R_1 | R_2 | \dots | R_n$ :

- $X_1 \dots X_k \in \mathcal{L}(R_i)$
- $X_1 \dots X_k \in \mathcal{L}(R_j)$

Which is the match to consider?

first one listed rule

Errors: to manage errors put as last match in the list a rexp for all lexemes not in the language

# LA matching rules

**Errors:** to manage errors put as last match in the list a rexp for all lexemes not in the language

# Finite Automata

- Regular Expressions = specification
- Finite Automata = implementation

A Finite Automata is a tuple:  $\langle \mathcal{S}, \Sigma, \delta, s_0, \mathcal{F} \rangle$

## DFA vs. NFA

Depending on the definition of  $\delta$  we distinguish between:

- Deterministic Finite Automata (DFA)
- Nondeterministic Finite Automata (NFA)

The transition relation  $\delta$  can be represented in a table (transition table)

Overview of the graphical notation circle and edges (arrows)

# Finite Automata

Depending on the definition of  $\delta$  we distinguish between:

- Deterministic Finite Automata (DFA)
- Nondeterministic Finite Automata (NFA)

The transition relation  $\delta$  can be represented in a table (transition table)

Overview of the graphical notation **circle and edges (arrows)**

# examples

- DFA for a single 1
- DFA for accepting any number of 1's followed by a single 0
- DFA for any sequence of a or b (possibly empty) followed by 'abb'

Which regexp correctly defines the automata:

- 1  $(0|1)^*$
- 2  $(1^*|0)(1|0)$
- 3  $1^*|(01)^*|(001)^*|(000^*1)^*$
- 4  $(0|1)^*00$

## DFA, NFA and $\epsilon$ -moves

- DFA

- one transition per input per state
- no  $\epsilon$ -moves
- faster

- NFA

- can have multiple transitions for one input in a given state
- can have  $\epsilon$ -moves
- smaller (exponentially)

## DFA, NFA and $\epsilon$ -moves

- DFA

- one transition per input per state
- no  $\epsilon$ -moves
- faster

- NFA

- can have multiple transitions for one input in a given state
- can have  $\epsilon$ -moves
- smaller (exponentially)

# From regexp to NFA

## Equivalent NFA for a regexp

- 1 for  $\epsilon$
- 2 for 'a'
- 3 for AB
- 4 for A|B
- 5 for A\*

Now consider the regexp for  $(1|0)^*1$
