# Cause-Effect Graphing

## CEG aka Dependency Modeling

The very general idea is to make explicit, also **through a graphical representation**, the relation among input conditions (**causes**) and output conditions (**effects**) and to exploit such relations for testing purposes.

In any case the relation can be fruitfully represented by a **boolean expression**

## Cause and effects

A **cause** is any condition in the requirements that may effect the program output. An **effect** is the response of the program to some combination of input conditions. An effect is **not necessarily visible** to the external user, while it can be retrieved introducing suitable probes (**test points**)

The LED close to the product description should be switched on when the credit becomes greater then the price of the snack

# Test generation from CEG

## CEG and test generation

- ▶ Identify cause and effects reading the requirements
- ▶ Express the relationship between causes and effects using a CEG
- ▶ Transform the CEG into a decision table
- ▶ Generate tests from the decision table

# CEG Notation

# Creating a CFG

## Process

To create a CFG follow the process below:

- ▶ carefully identify causes and effects from a thoughtful **analysis of the requirements**.
- ▶ assign to each cause and each effect a **unique identifier**
- ▶ represent the **identified relations** in a CFG

# Example

## Computer purchase system

A web based company sells computers (CPU), printers (PR), monitors (M), and additional memories (RAM).

**Conditions:** For each order the buyer may select from 3 CPU, 2 PR, 3M. RAM one unit in one order. M20 and M23 any CPU or as stand alone. M30 only with CPU 3. PR 1 is available free with CPU 2 or 3. M and PR can pbe purchased as stand alone. Non M30. CPU 1 gets RAM 256 upgrade. CPU 2 o 3 gets RAM 512 upgrade. RAM 1G upgrade and free PR2 available if CPU 3 purchased with M30.

There is a window to make selection with menus in particular a widget displaying the free item available and a “Price” widget reports the calculation related to prices.

Causes are the purchase of the items

Effects are the status of the various windows

# Example

## Computer purchase system

A web based company sells computers (CPU), printers (PR), monitors (M), and additional memories (RAM).

**Conditions:** For each order the buyer may select from 3 CPU, 2 PR, 3M. RAM one unit in one order. M20 and M23 any CPU or as stand alone. M30 only with CPU 3. PR 1 is available free with CPU 2 or 3. M and PR can pbe purchased as stand alone. Non M30. CPU 1 gets RAM 256 upgrade. CPU 2 o 3 gets RAM 512 upgrade. RAM 1G upgrade and free PR2 available if CPU 3 purchased with M30.

There is a window to make selection with menus in particular a widget displaying the free item available and a “Price” widget reports the calculation related to prices.

**Causes** are the purchase of the items

**Effects** are the status of the various windows

# Decision Tables from a CEG

CEG models relations among different aspects of the system. The derivation of test requires the definition of the corresponding **decision table**

## Decision tables

For each cause and effect use a row and put test as columns of the matrix. Each entry in the decision table is a 0 or a 1 depending on whether or not the corresponding condition is false or true, respectively.

# How to derive a DT

**Input:** A CEG containing causes  $C_1, C_2, \dots, C_p$  and effects  $Ef_1, Ef_2, \dots, Ef_q$

**Output:** A decision table containing  $p + q$  rows and  $M$  columns where  $M$  depends on relationship between causes and effects.

## Procedure CFG2DT

**Step1:** Initialize DT to an empty DT

**Step2:** Execute the following steps for  $i=1$  to  $q$

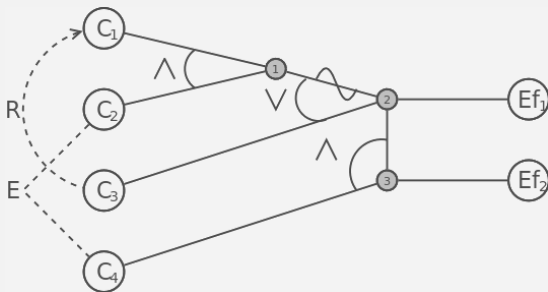

**2.1** Select the next effect  $e$

**2.2** Find combinations of conditions that cause  $e$  to be present and store the  $m$  generated vector

**2.3** update the decision table adding the generated vectors

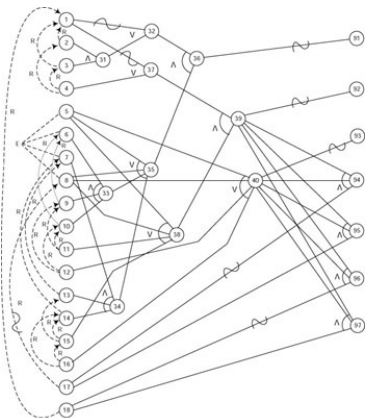

# DT derivation

Consider the following CEG and derive the corresponding decision table:

# Example

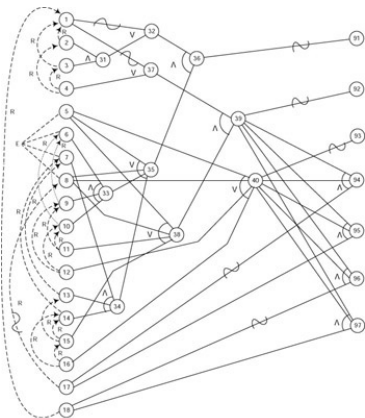

Apply the procedure to the following CEG:

You need to automatize the process. In your opinion which should be the main component included in a supporting tool?

# Example

Apply the procedure to the following CEG:

You need to automatize the process. In your opinion which should be the main component included in a supporting tool?

# Heuristic to avoid combinatorial explosion

The described approach could lead to **exponential generation** on the number of tests with respect to causes. Indeed having an effect depending on  $n$  causes can lead to the generation of a **number of vectors in the order of  $2^n$**

## Reduction strategies

- ▶ For **or** relations: enumerate just those situations in which two causes are both false or one of them true
- ▶ For **and** relations: enumerate those situations for which causes assume different values, and those in which all of them are true.

# Test generation

## Tests from a decision table

Each column of the decision table constitutes the source for generating tests. Consider that each condition could be satisfied by more assignment to the variable leading to the generation of more than one test for each column

# Test generation from predicates

Techniques aiming at finding bugs in the **coding of conditions**

## Predicate testing

*if the printer is ON and has paper then send the document for printing*

```
pr: (printer_status=ON)  $\wedge$  printer_tray!=empty
```

Consider the following predicate:

$$(a < b) \vee (c > d) \wedge e$$

The following test:

$$t = (a = 1, b = 2, c = 4, d = 2, e = \text{true})$$

results in

$$p(t) = \text{true}$$

# Fault model

Which kind of faults are generally targeted:

- **Boolean operator fault**
  - incorrect boolean operator used
  - negation missing or placed incorrectly
  - parentheses are incorrect
  - incorrect Boolean variable used
  - missing or extra Boolean variable
- **relational operator fault**
  - incorrect relational operator is used
- **arithmetic expression fault**
  - arithmetic expression is off by an amount equal to  $\epsilon$  (off-by- $\epsilon$ , off-by- $\epsilon^+$ , off-by- $\epsilon^*$ )

## Objective of predicate testing

To generate a test set  $\mathcal{T}$  such that there is at least one test cast  $t \in \mathcal{T}$  for which  $p_c$  and its faulty version  $p_f$  are distinguishable

# Fault model

Which kind of faults are generally targeted:

- **Boolean operator fault**
  - incorrect boolean operator used
  - negation missing or placed incorrectly
  - parentheses are incorrect
  - incorrect Boolean variable used
  - missing or extra Boolean variable
- **relational operator fault**
  - incorrect relational operator is used
- **arithmetic expression fault**
  - arithmetic expression is off by an amount equal to  $\epsilon$  (off-by- $\epsilon$ , off-by- $\epsilon^+$ , off-by- $\epsilon^*$ )

## Objective of predicate testing

To generate a test set  $\mathcal{T}$  such that there is at least one test cast  $t \in \mathcal{T}$  for which  $p_c$  and its faulty version  $p_i$  are distinguishable

# Predicate testing criteria

## Three common criteria:

- **BOR (Boolean Operator)**: A test set  $\mathcal{T}$  that satisfied the BOR-testing criterion for a compound predicate  $p_r$ , guarantees the detection of single or multiple Boolean operator faults in the implementation of  $p_r$ .  $\mathcal{T}$  is referred to as a BOR-adequate test set and sometimes written as  $\mathcal{T}_{BOR}$ .
- **BRO (Boolean and relational Operator)**: A test set  $\mathcal{T}$  that satisfied the BRO-testing criterion for a compound predicate  $p_r$ , guarantees the detection of single or multiple Boolean operator and relational operator faults in the implementation of  $p_r$ .  $\mathcal{T}$  is referred to as a BRO-adequate test set and sometimes written as  $\mathcal{T}_{BRO}$ .
- **BRE (Boolean and relational expression)**: A test set  $\mathcal{T}$  that satisfied the BRE-testing criterion for a compound predicate  $p_r$ , guarantees the detection of single or multiple Boolean operator, relational operator and arithmetic expression faults in the implementation of  $p_r$ .  $\mathcal{T}$  is referred to as a BRO-adequate test set and sometimes written as  $\mathcal{T}_{BRE}$ .

# BOR example

Let  $p_r : a < b \wedge c > d$  and  $\mathcal{S}$  constraints on  $p_r$  where  $\mathcal{S} = \{(\mathbf{t}, \mathbf{t}), (\mathbf{t}, \mathbf{f}), (\mathbf{f}, \mathbf{t})\}$  the following test set  $\mathcal{T}$  satisfies constraint set  $\mathcal{S}$  and the BOR-testing criterion:

$$\mathcal{T} = \{t_1 : \langle a = 1, b = 2, c = 1, d = 0 \rangle ; \\ t_2 : \langle a = 1, b = 2, c = 1, d = 2 \rangle ; \\ t_3 : \langle a = 1, b = 0, c = 1, d = 0 \rangle ; \\ \}$$

## Covered faults

To discover the covered faults lets modify the proposition introducing one or more operational fault

# Generating BOR, BRO, BRE adequate tests

A **predicate constraint**  $C$  for predicate  $p_r$  is a sequence of  $n + 1$  boolean and relational symbols.

A **test case**  $t$  **satisfies**  $C$  for predicate  $p_r$ , if each component of  $p_r$  satisfies the corresponding constraint in  $C$  when evaluated against  $t$ .  
e.g.: given  $p_r = b \wedge r < s \vee u \geq v$  and  $C : (t, =, >)$  the following test case satisfies  $C$ :  $\langle b = true, r = 1, s = 1, u = 1, v = 0 \rangle$

There exist algorithms for the generation of adequate tests given constraints on the predicate. They are based on the definition of:

- Cartesian product of sets
- *onto* set product operator
- $AST(p_r)$

# Onto Operator

## Onto Operator

Given two sets  $A$  and  $B$  the onto operator constructs the minimal set of pairs  $\langle a, b \rangle$  where  $a \in A$  and  $b \in B$  and each element of the two sets is used in at least one of the pairs in the onto set  $A \otimes B$ .

Which is the cardinality of the onto set?

Let  $A = \{t, 0, >\}$  and  $B = \{f, <\}$  lets derive the cartesian product and some example of onto product set

# Abstract Syntax Tree for a Predicate $p$

## AST

The abstract syntax tree provides a tree based representation of a predicate that is typically useful for associating meaning to the predicate itself.

Leaf of the tree are atomic proposition while nodes are boolean operators

## AST

Let's build the AST for the proposition:

$$a < b \vee q \wedge \neg p \vee (a == c \wedge p)$$

# Generating the BOR-constraint set

Let  $p_r$  be a predicate and  $AST(P_r)$  its abstract syntax tree,  $S_N$  the constraint set attached to a node  $N$  (where  $S_N^t$  and  $S_N^f$  are the true and false constraints associated with the node). The following alg. generates the BOR-constraint set for  $p_r$

**Input:**  $AST(p_r)$  (only singular expressions)

**Output:** BOR-Constraint set attached to the root node

- 1 Label each leaf node  $N$  of  $AST(p_r)$  with its constraint set  $S_N = \{t, f\}$
- 2 Visit the  $AST$  bottom-up. Let  $N_1$  and  $N_2$  direct descendants of node  $N$  and  $S_{N_1}$  and  $S_{N_2}$  the corresponding BOR-constraint set.  $S_N$  is computed as follows:

2.1  $N$  is an OR-node:

- $S_N^f = S_{N_1}^f \otimes S_{N_2}^f$
- $S_N^t = (S_{N_1}^t \times \{f_2\}) \cup (\{f_1\} \times S_{N_2}^t)$  where  $f_1 \in S_{N_1}^f$  and  $f_2 \in S_{N_2}^f$

2.2  $N$  is an AND-node:

- $S_N^t = S_{N_1}^t \otimes S_{N_2}^t$
- $S_N^f = (S_{N_1}^f \times \{t_2\}) \cup (\{t_1\} \times S_{N_2}^f)$  where  $t_1 \in S_{N_1}^t$  and  $t_2 \in S_{N_2}^t$

2.3  $N$  is NOT-node:

- $S_N^t = S_{N_1}^f$
- $S_N^f = S_{N_1}^t$

# BOR-constraint set example

Let's apply the BOR-constraint procedure to:

- $(a + b < c) \wedge \neg p \vee (r > s)$

# Generating the BRO-constraint set

**Input:**  $AST(p_r)$  (only singular expressions)

**Output:** BRO-Constraint set attached to the root node

- 1 Label each leaf node  $N$  of  $AST(p_r)$  with its constraint set  $S_N$ . For each leaf node that represents a Boolean variable  $S_N = \{t, f\}$ . For each leaf node that is a relational expression  $S_N = \{(>), (=), (<)\}$ .
- 2 Visit the  $AST$  bottom-up. Let  $N_1$  and  $N_2$  direct descendants of node  $N$  and  $S_{N_1}$  and  $S_{N_2}$  the corresponding BRO-constraint set.  $S_N$  is computed as done for the BOR procedure.

Let's apply the BRO-constraint procedure to:

- $(a + b < c) \wedge \neg p \vee (r > s)$

# Generating the BRO-constraint set

**Input:**  $AST(p_r)$  (only singular expressions)

**Output:** BRO-Constraint set attached to the root node

- 1 Label each leaf node  $N$  of  $AST(p_r)$  with its constraint set  $S_N$ . For each leaf node that represents a Boolean variable  $S_N = \{t, f\}$ . For each leaf node that is a relational expression  $S_N = \{(>), (=), (<)\}$ .
- 2 Visit the  $AST$  bottom-up. Let  $N_1$  and  $N_2$  direct descendants of node  $N$  and  $S_{N_1}$  and  $S_{N_2}$  the corresponding BRO-constraint set.  $S_N$  is computed as done for the BOR procedure.

Let's apply the BRO-constraint procedure to:

- $(a + b < c) \wedge \neg p \vee (r > s)$

# Generating the BRE-constraint set

**Input:**  $AST(p_r)$  (only singular expressions)

**Output:** BRE-Constraint set attached to the root node

- 1 Label each leaf node  $N$  of  $AST(p_r)$  with its constraint set  $S_N$ . For each leaf node that represents a Boolean variable  $S_N = \{t, f\}$ . For each leaf node that is a relational expression  $S_N = \{(+\epsilon), (=), (-\epsilon)\}$ .
- 2 Visit the  $AST$  bottom-up. Let  $N_1$  and  $N_2$  direct descendants of node  $N$  and  $S_{N_1}$  and  $S_{N_2}$  the corresponding BRE-constraint set.  $S_N$  is computed as done for the BOR procedure.

Constraint	Satisfying condition
$+\epsilon$	$0 < e_1 - e_2 \leq +\epsilon$
$-\epsilon$	$-\epsilon \leq e_1 - e_2 < 0$

Let's apply the BRE-constraint procedure to:

•  $(a + b < c) \wedge \neg p \vee (r > s)$

# Generating the BRE-constraint set

**Input:**  $AST(p_r)$  (only singular expressions)

**Output:** BRE-Constraint set attached to the root node

- 1 Label each leaf node  $N$  of  $AST(p_r)$  with its constraint set  $S_N$ . For each leaf node that represents a Boolean variable  $S_N = \{t, f\}$ . For each leaf node that is a relational expression  $S_N = \{(+\epsilon), (=), (-\epsilon)\}$ .
- 2 Visit the  $AST$  bottom-up. Let  $N_1$  and  $N_2$  direct descendants of node  $N$  and  $S_{N_1}$  and  $S_{N_2}$  the corresponding BRE-constraint set.  $S_N$  is computed as done for the BOR procedure.

Constraint	Satisfying condition
$+\epsilon$	$0 < e_1 - e_2 \leq +\epsilon$
$-\epsilon$	$-\epsilon \leq e_1 - e_2 < 0$

Let's apply the BRE-constraint procedure to:

- $(a + b < c) \wedge \neg p \vee (r > s)$

# CEG and Predicate testing

## CEG

- CEG strategy to define relations among causes and effects (“oracles”)
- Decision table technique to identify test cases

## Predicate testing

## Predicate testing

- Strategies for deriving test from predicates, fault coverage guarantees

“Better together”

# Usage of predicate testing techniques

Approaches to test set derivation from predicates can be applied considering different starting points:

- ▶ Specification based testing
- ▶ Program based testing

The different settings have different consequences

## Exercise

Consider the BOR, BRO, BRE criteria for testing predicates including expressions and relational operator, and shortly introduce their objectives and differences. Use the most appropriate criteria for singular expressions to generate a test set, able to discover logical, and relational faults, for the following compound predicate (possibly transforming it):

$$\neg((x \cdot z) \geq (y + z) \wedge \neg p) \wedge ((z = w) \vee p)$$
